How a search becomes matching passages

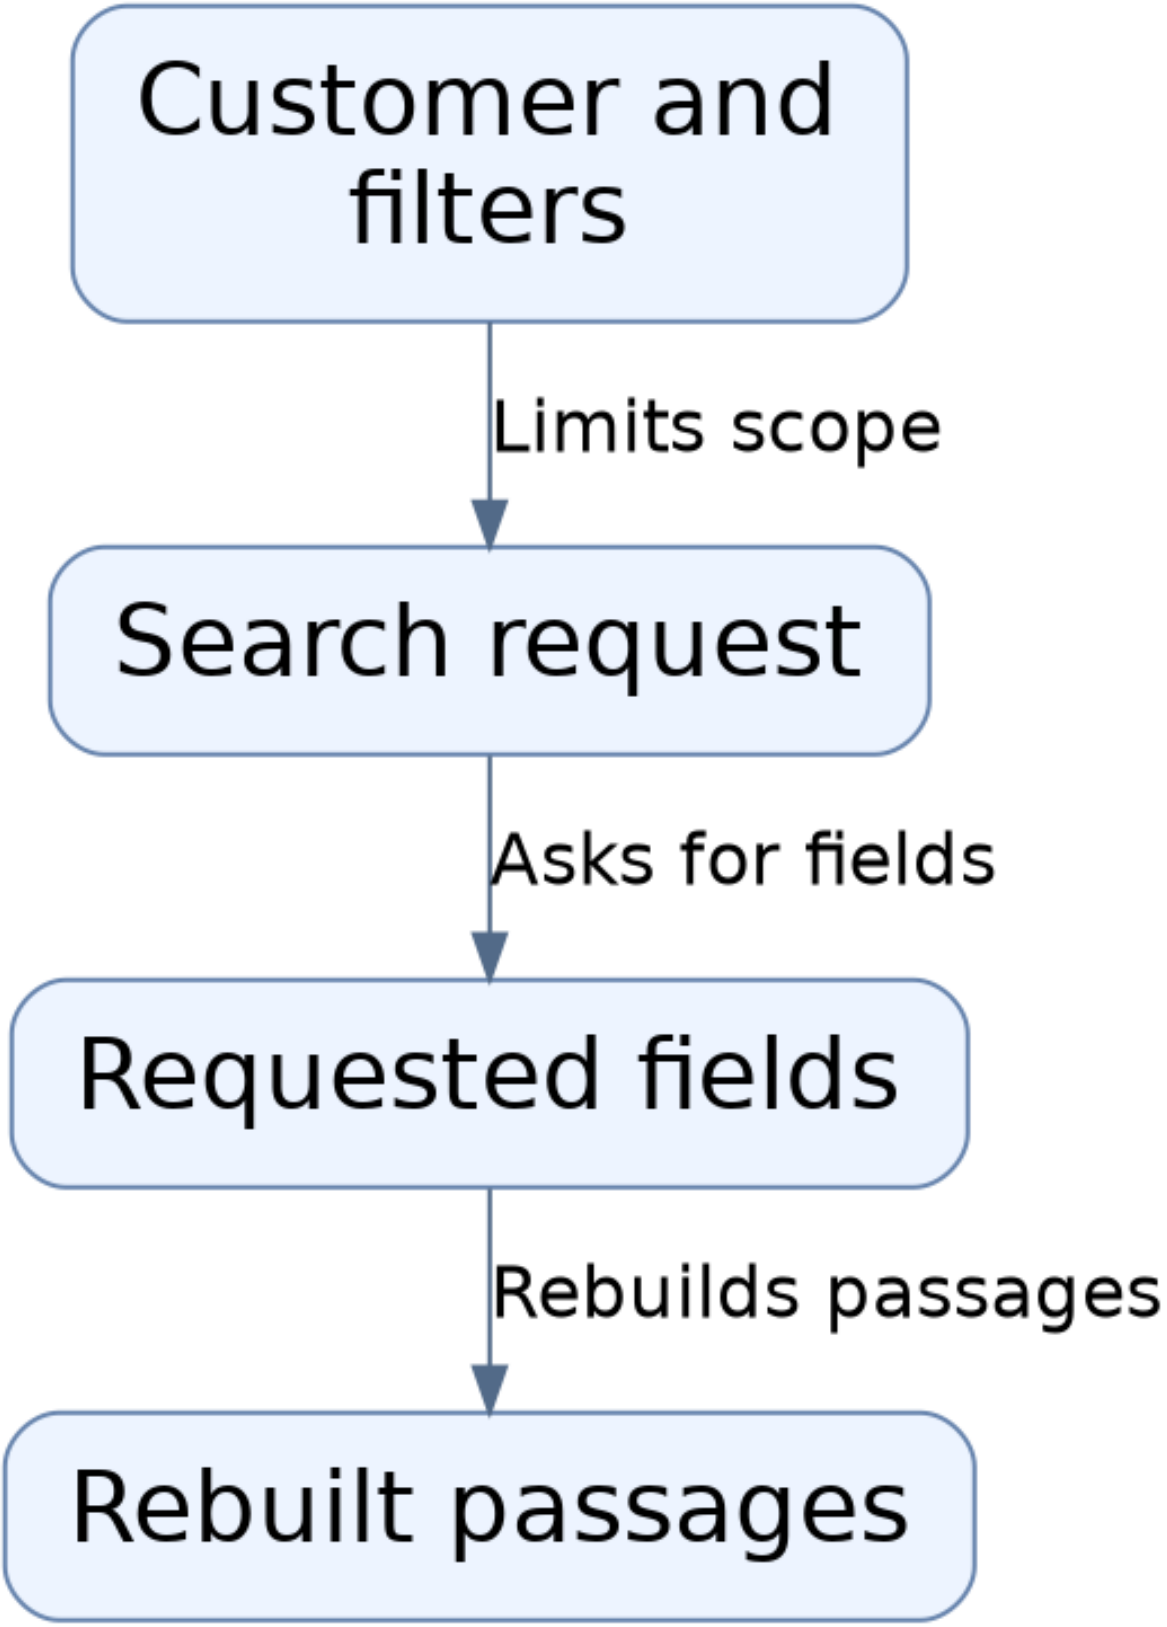

A search phrase is cleaned, sent out to be turned into numbers, used to find the closest stored passages in the search index, and returned as passages with optional diagnostic detail.

Keeping one customer's material separate

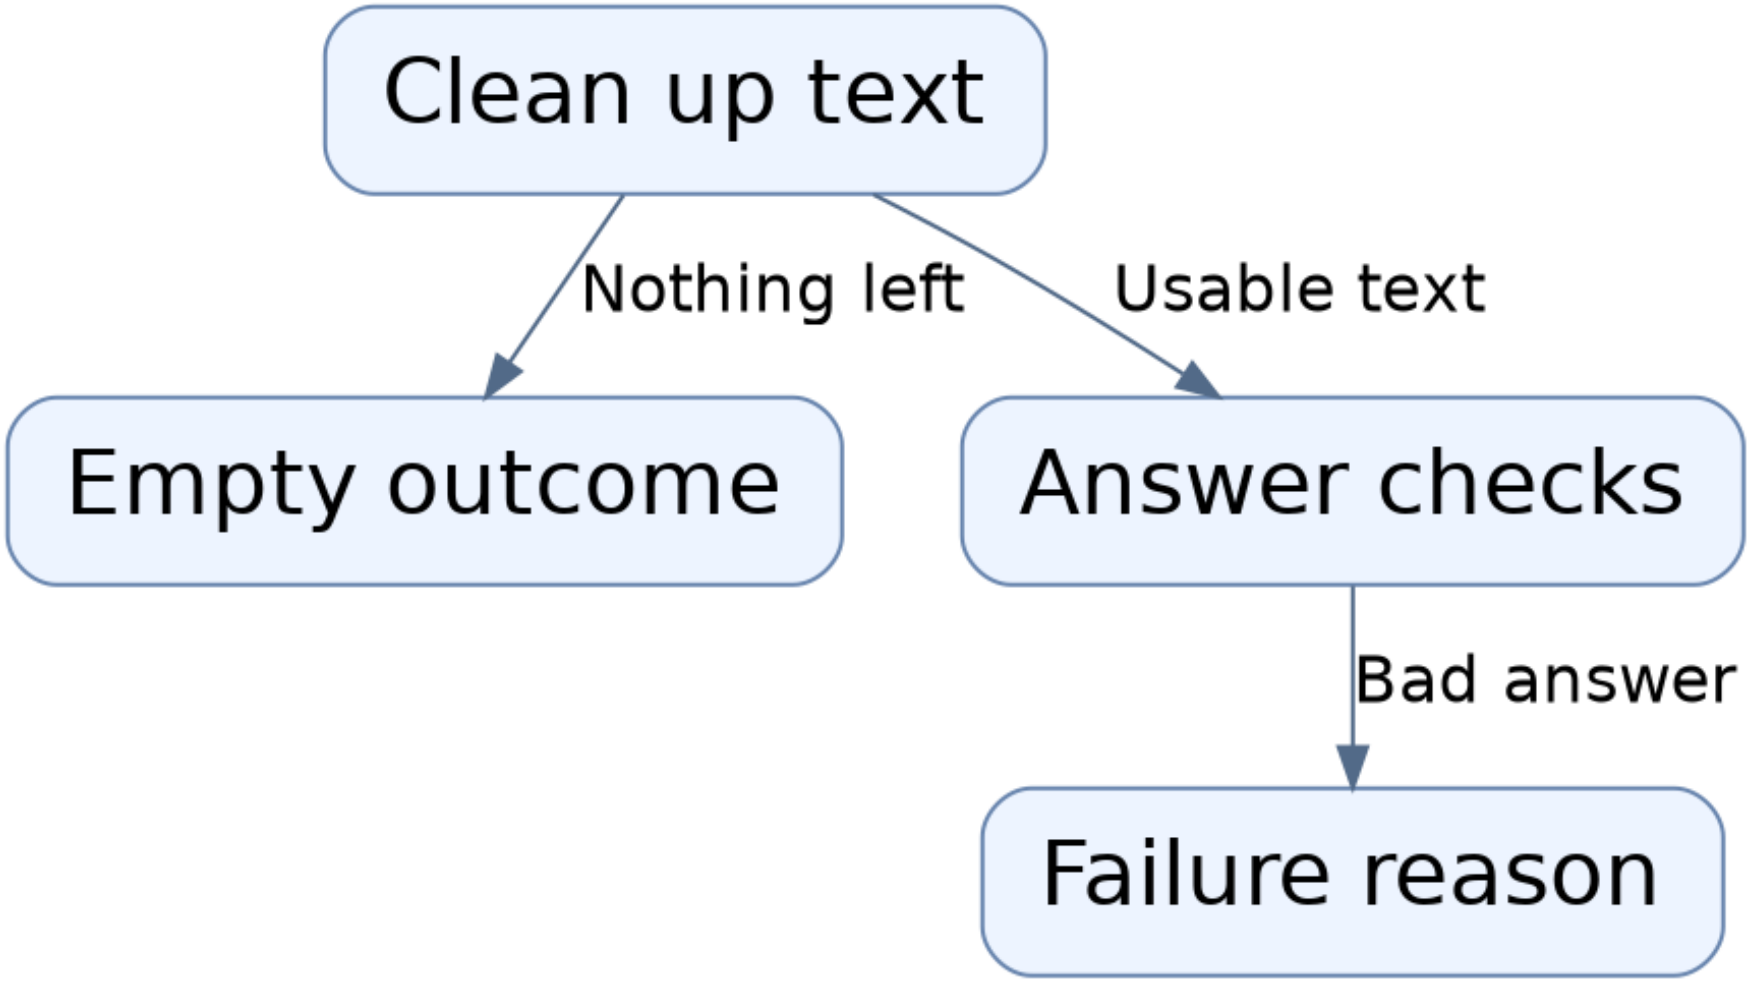

Customer and filter details are applied inside the search request itself, so only that customer's own passages are considered, and the requested fields are enough to rebuild each passage for callers.

What happens with empty or unusable input

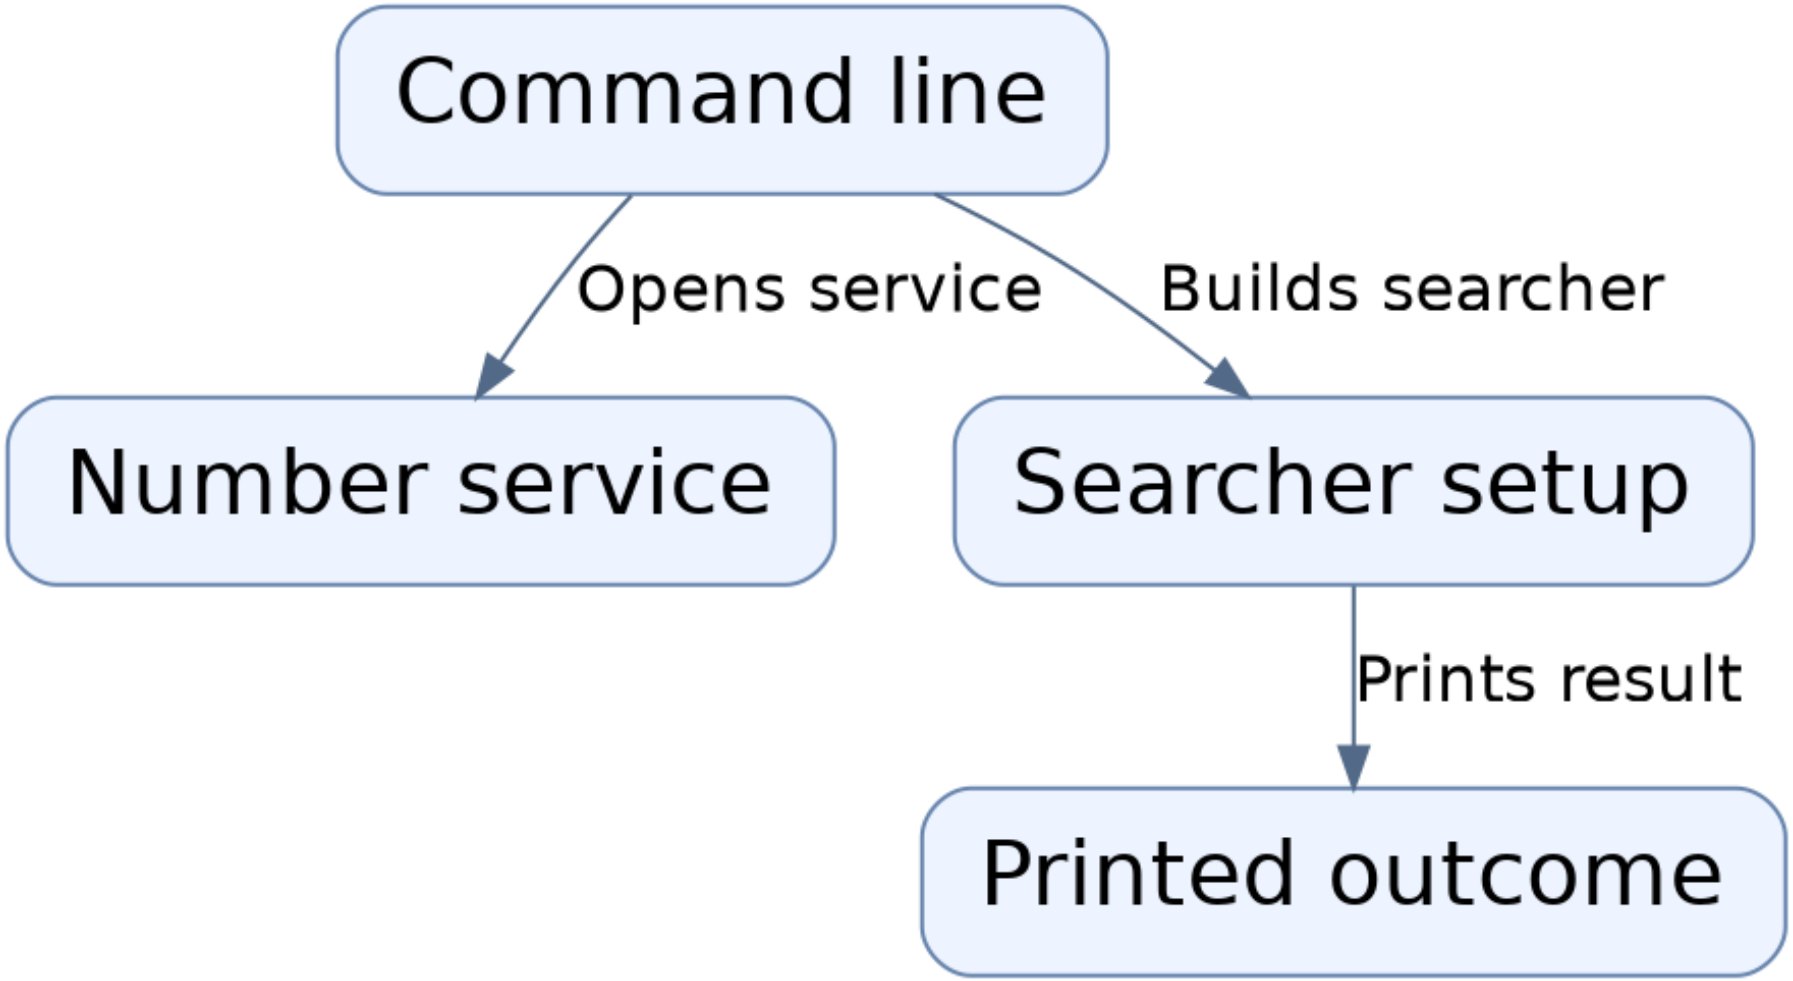

Blank text returns nothing without contacting any outside service, while mismatched or malformed answers from the number service and search index stop the flow with a clear failure reason.

How a developer runs it today

A command-line tool takes a search phrase with a required customer identifier and optional collection and size, opens the outside number service, builds the searcher, and prints the outcome with extra explanation switched on.
