# Architecture

Dataset loading, corpus preparation, evaluation search, scoring, and reporting modules, plus CLI, debug API, and storage surfaces.

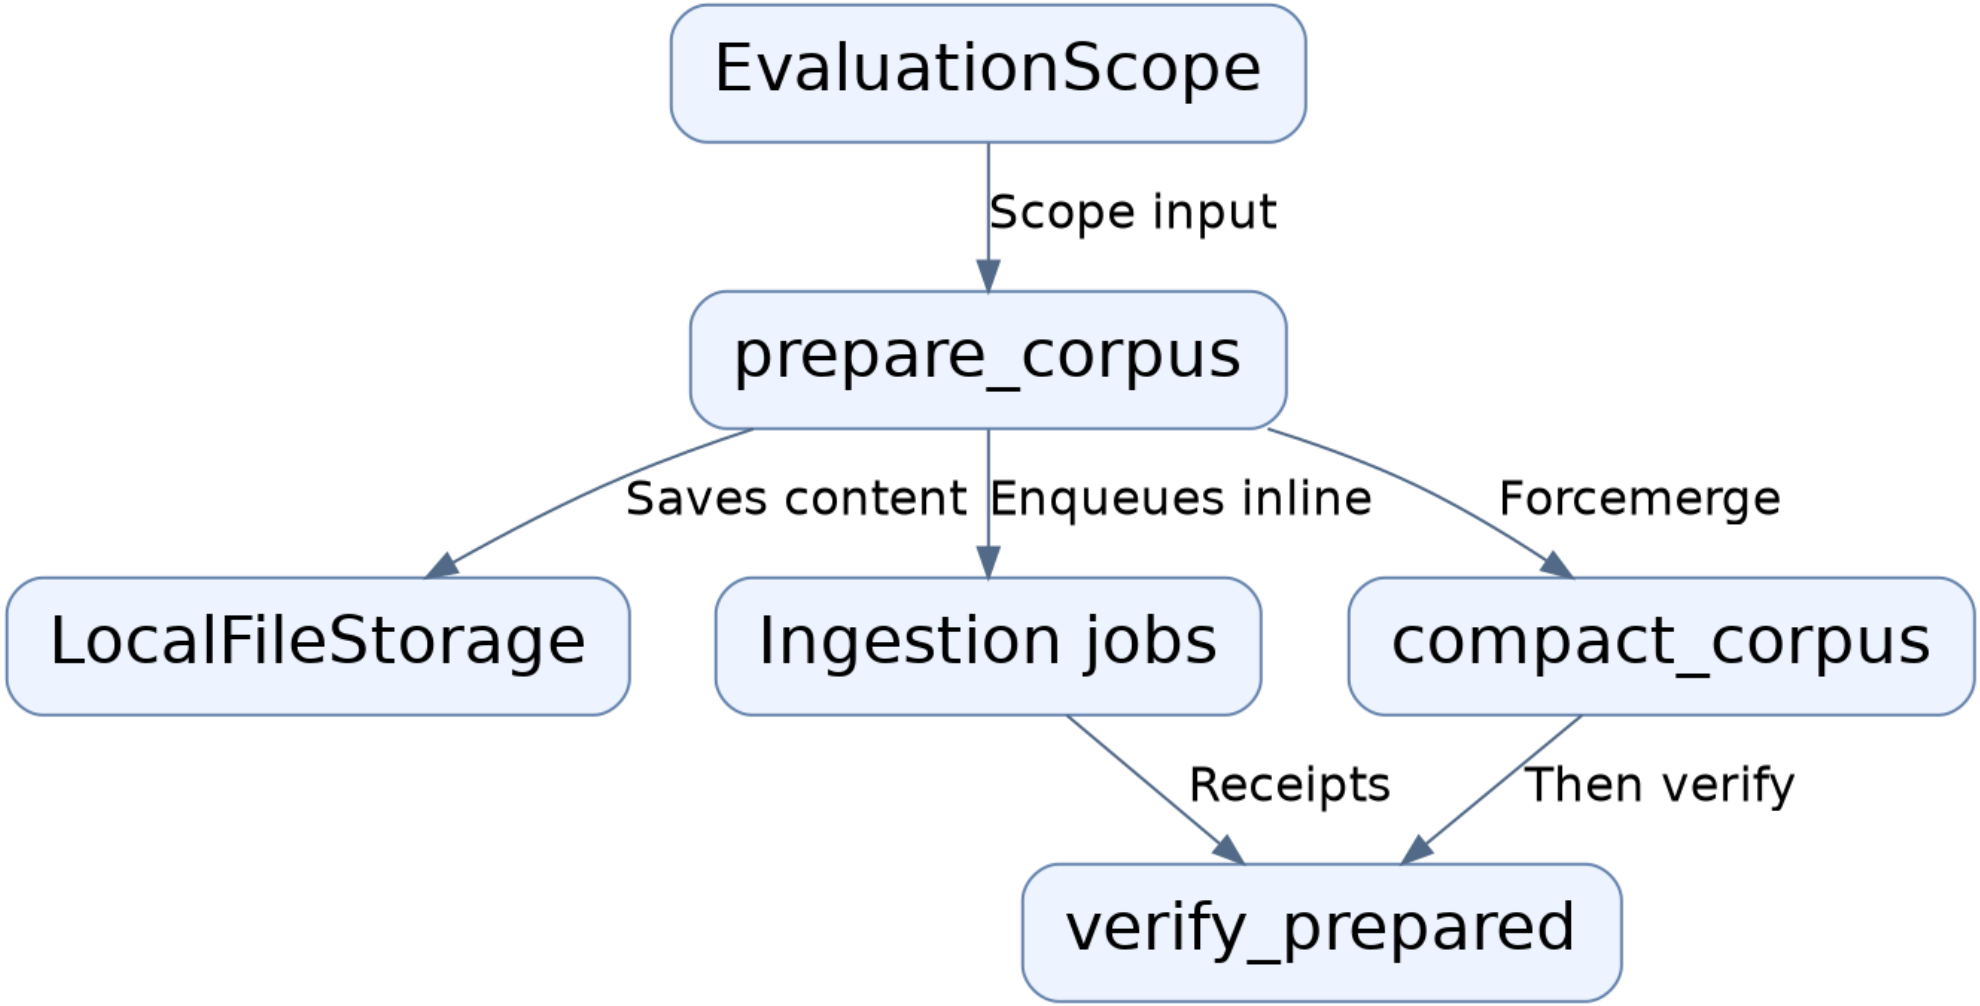

# Dataset loading and validation

load_dataset reads the manifest, verifies file hashes, parses JSONL rows, enforces uniqueness, and cross-validates judgments against corpus and queries.

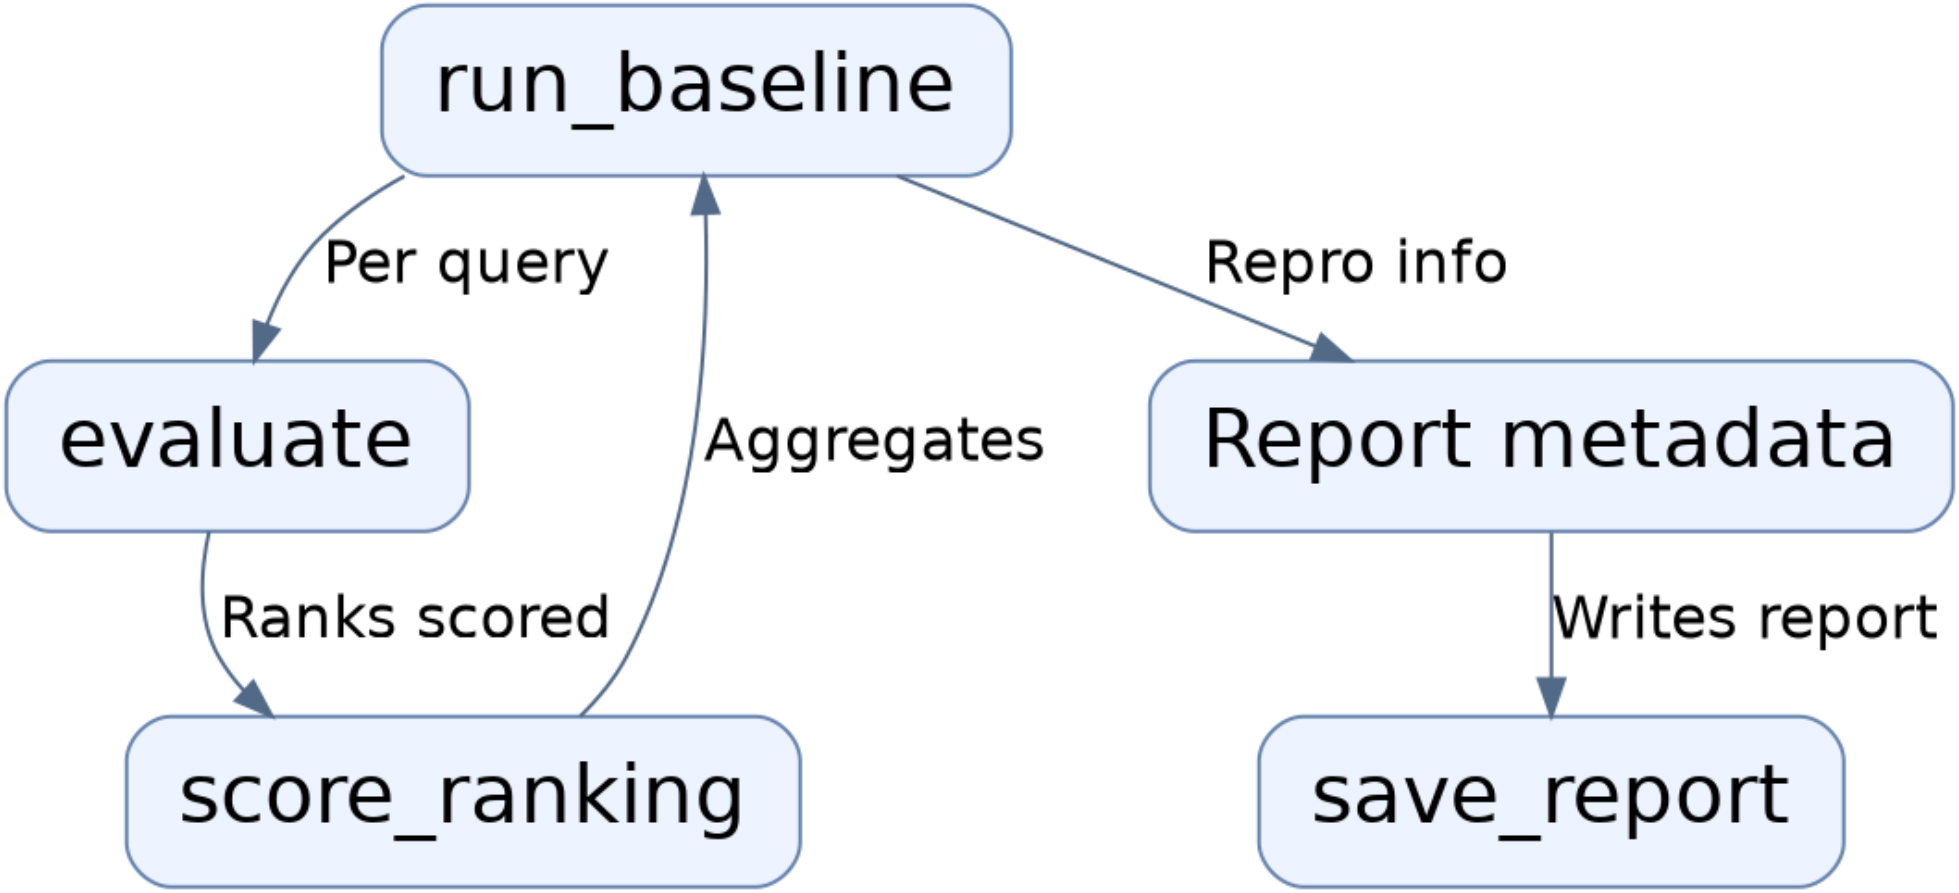

# Corpus preparation flow

prepare_corpus computes scope, writes content to storage, enqueues inline durable jobs, then compacts and verifies the index against job receipts.

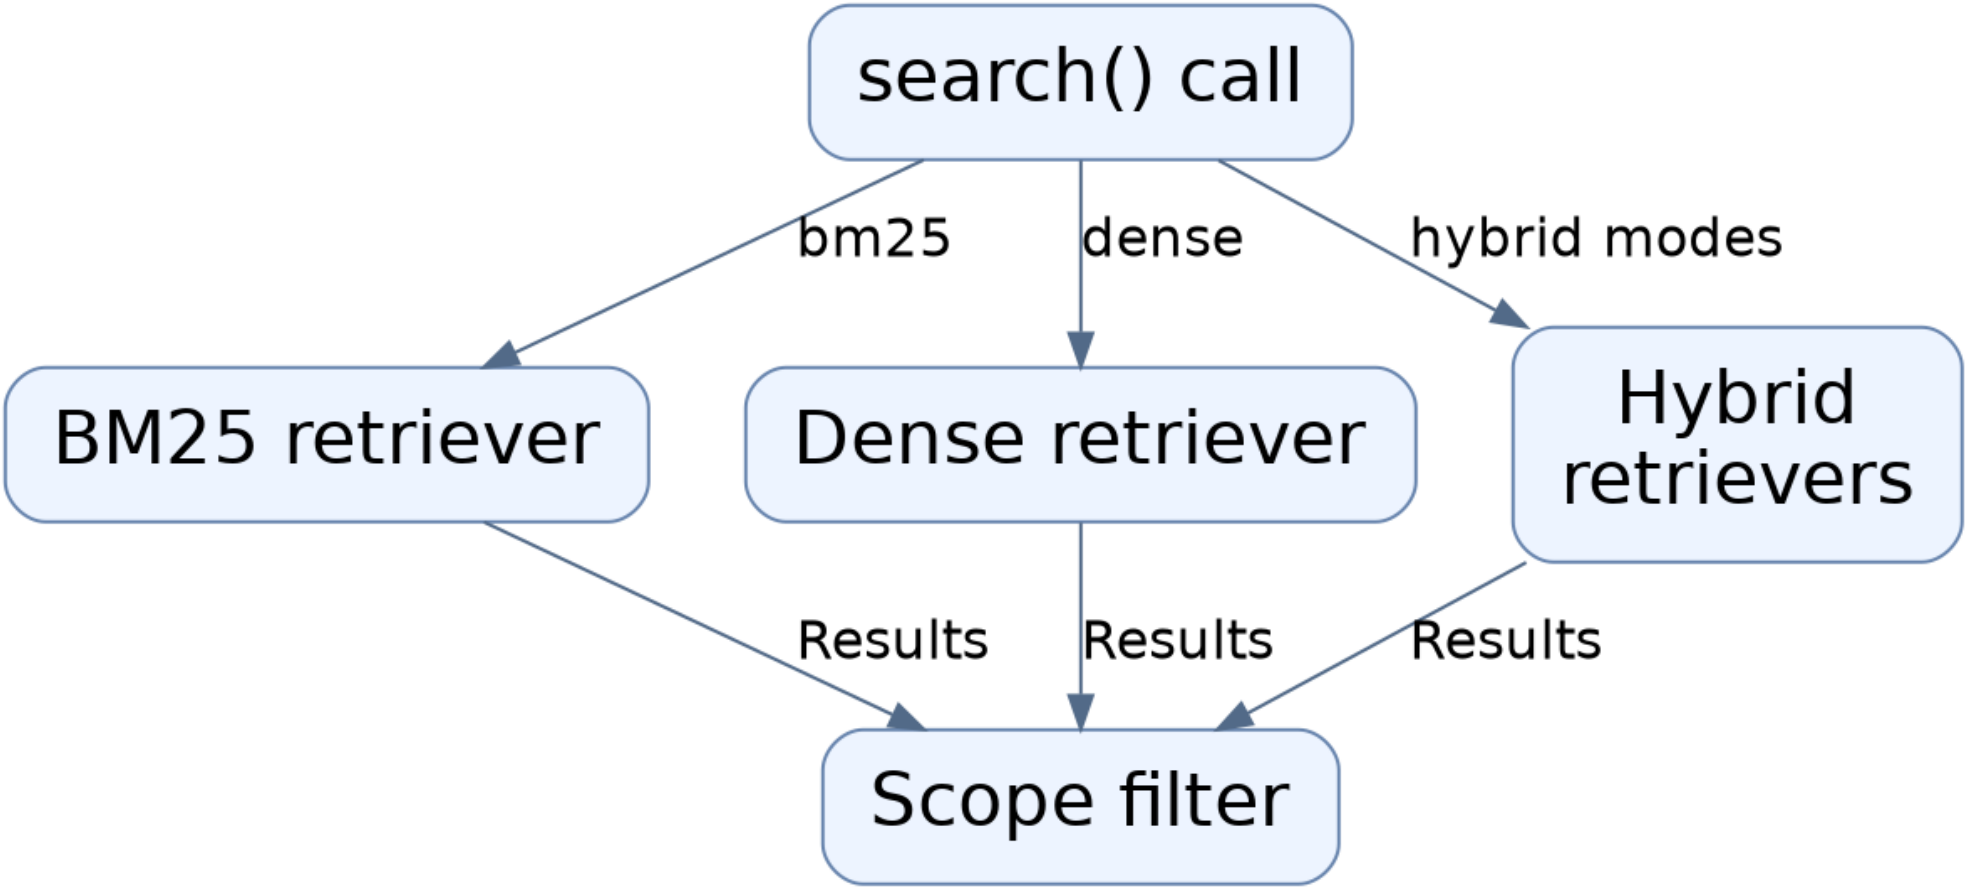

# Evaluation run flow

run_baseline prepares scope, calls evaluate for each mode, scores rankings, records reproduction metadata, and saves JSON plus markdown reports.

# Search mode dispatch

EvaluationSearch validates mode and filters, derives scope, dispatches to the appropriate retriever (lazy provider contexts), then filters and deduplicates results.

# SciFact dataset build

The scifact CLI downloads and hash-verifies the archive, converts it into a normalized dataset, and optionally builds a deterministic 30-query/500-doc subset re-validated by load_dataset.
