Architecture

The FastAPI app reads shared Settings and mounts the evaluation router; the backend image runs it via uvicorn, while Makefile and CI drive migrations and tests against the same Base and config.

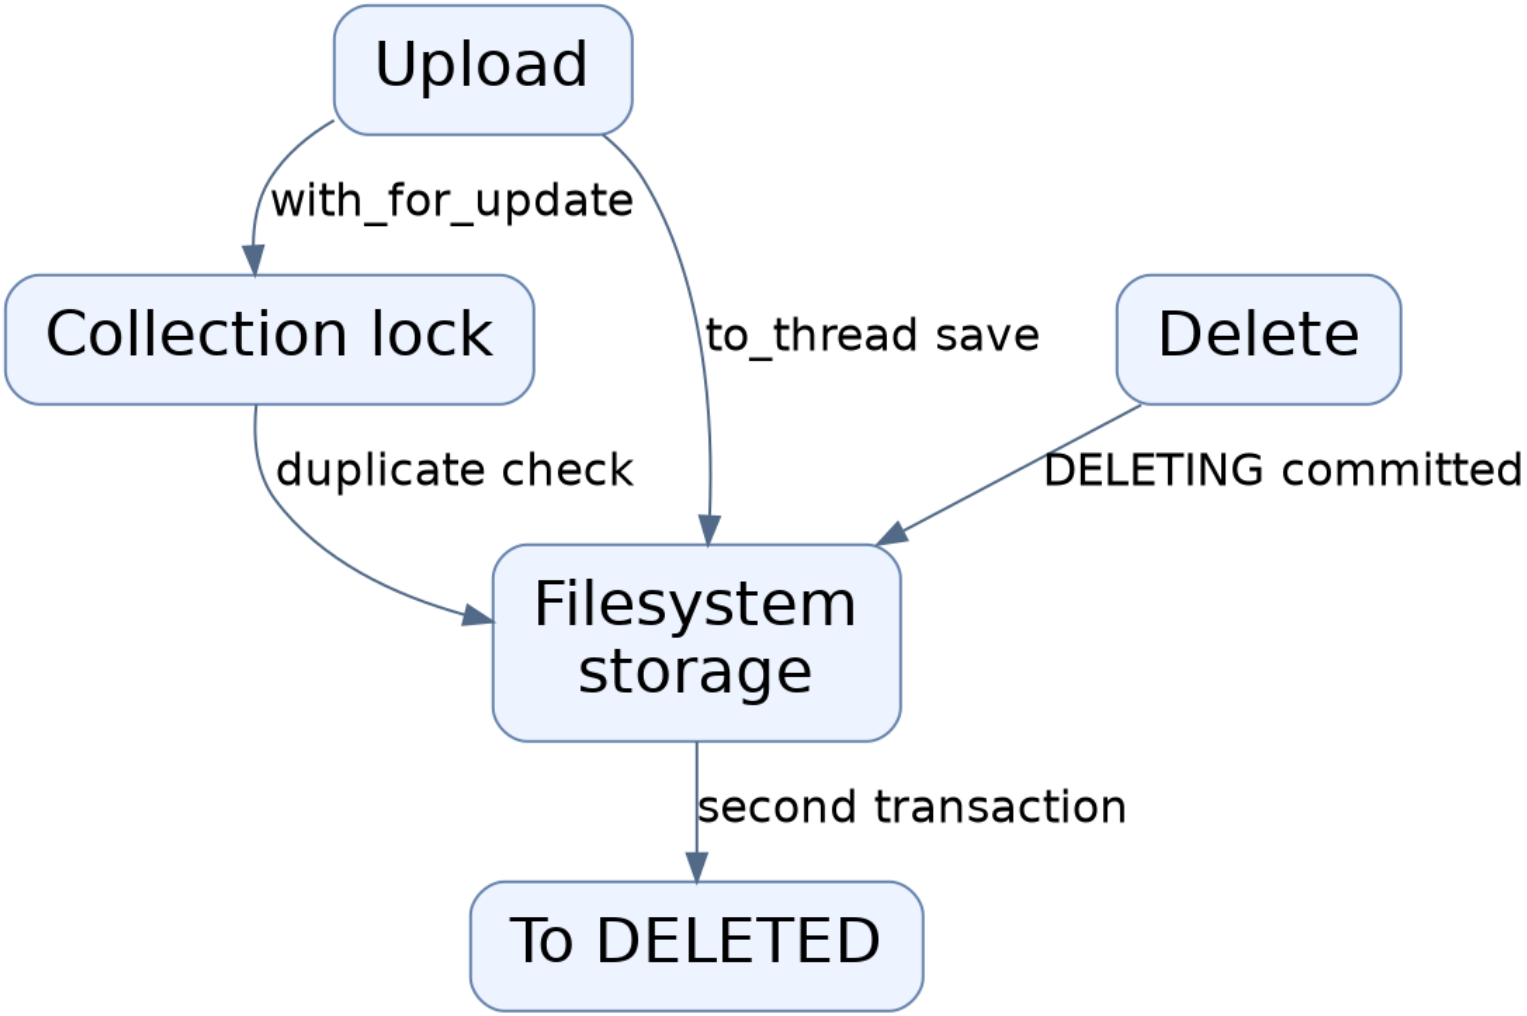

Health and readiness

Liveness shares one handler across two paths; readiness fans out concurrent probes whose boolean results decide 200 versus 503, isolating partial dependency failure.

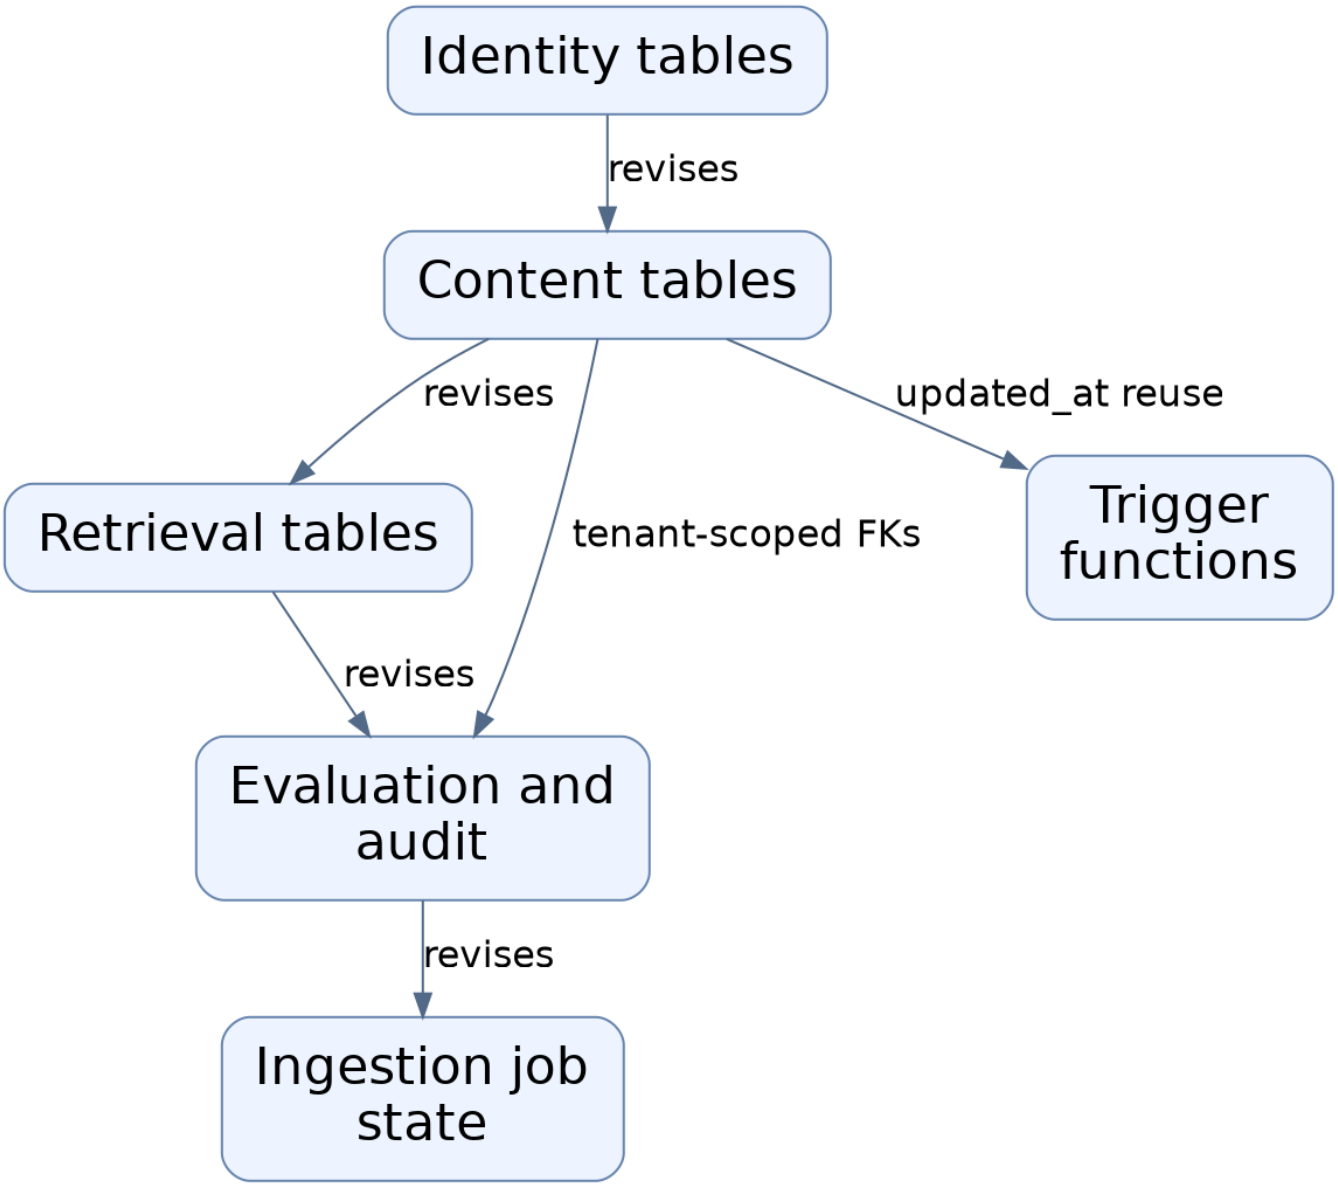

Document lifecycle

DocumentService owns its transactions: upload locks the collection for dedupe and saves files off the event loop; delete commits intent before removing storage, acknowledging non-atomic DB and disk.

Schema ownership

Linear Alembic revisions add schema domains; tenant-scoped composite foreign keys enforce ownership, while immutability triggers push retrieval-config, evaluation, judgment, and audit invariants into PostgreSQL.

Local and CI verification

Makefile and CI share a local PostgreSQL plus OpenSearch service topology: migrations run first, then seed, then integration and live-provider tests are exercised.
